Appendix B: Random Signal Analysis 313 transformation (which can be linear or nonlinear, memoryless or with memory) of the original random variable. Therefore, let  $x$  be a random variable with known distribution  $F_x(x)$  and let  $g(x)$  be a function, we wish to find the distribution of the new random variable  $y = g(x)$ . The distribution of  $y$  is then ...

To create the signal,  $x_1$  in this case, these values were chosen for the waveform parameters: For the random signal case,  $A$  is nominally 1.5, but a random number uniform over  $(-0.5, 0.5)$  is added to  $A$ , making the composite sinusoid amplitude random. The frequency is fixed at 1.0, and the phase is uniform over. Five realizations of

We will also discuss some practical analysis applications of random processes and noise in different fields, e.g., calculating signal-to-noise ratios in communication systems. If time permits we will also describe Wiener-Hopf filtering and the Karhunen-Loeve expansion at the end of the course..

### RANDOM SIGNALS AND NOISE - Columbia University

RANDOM SIGNALS Signals can be divided into two main categories - deterministic and random. The term random signal is used primarily to denote signals, which have a random in its nature source. As an example we can mention the thermal noise, which is created by the random movement of electrons in an electric conductor. Apart from this,

Kurtosis measurement: Kurtosis gives you a measure of the "spikedness" of a random signal. Signals with a higher kurtosis value have more peaks that are greater than three times the signal's root mean square (RMS) value. In vibration analysis, kurtosis is used to monitor fatigue development in rolling bearings with a simple instrument.

Random vibration can be represented in the frequency domain by a power spectral density

function. The typical units are acceleration [ $G^2/\text{Hz}$ ] versus frequency [Hz]. The acceleration can also be...

## What is PSD expressed in G acceleration?

The correlation between two signals is a measure of how similarly shaped they are. The definition of correlation  $R_{12}$  for two signals  $x_1(t)$  and  $x_2(t)$ , at least one of which is an energy signal, is the area under the product of  $x_1(t)$  and  $x_2^*(t)$   $R_{12} = \int_{-\infty}^{\infty} x_1(t)x_2^*(t)dt$ . If we applied this definition to two power signals,  $R_{12} \dots$

Complex exponential signals play an important and unique role in the analysis of LTI systems both in continuous and discrete time. Complex exponential signals are the eigenfunctions of LTI systems. The eigenvalue corresponding to the complex exponential signal with frequency  $\omega$  is  $H(j\omega)$ , where  $H(j\omega)$  is the Fourier transform of the impulse ...

## Frequency Analysis of Signals and Systems

For random vibration analysis, units of  $g^2/\text{Hz}$  are frequently used for the PSD of acceleration. Here  $g$  denotes the g-force. Mathematically, it is not necessary to assign physical dimensions to the signal or to the independent variable.

## Spectral density - Wikipedia

Such signals can be described as 'weighted sums of complex exponentials' and are thus highly predictable in the following sense: given the Fourier transform of a signal we can work out exactly what the value of that signal would be at any time  $t$ . In practical applications other signals are encountered which are not amenable to such a ...

The text then progresses to more difficult subjects like random signals and does a reasonably good job at delivering understanding. In fact, this book has one of the better discussions of statistical signal processing that I have ever seen. This largely stems from a very large number of worked examples that are of great assistance.
